The National Tonsil Surgery Register in Sweden

Introduction

In a number of respects, 2013 has represented a breakthrough for the Swedish Tonsil Surgery Register. During the past year, some 82% of the tonsil operations performed in Sweden were registered. This means that the register is representative in describing the clinical activities for the tonsil surgery process. The register can be used as a tool for measuring improvements in quality over time and in comparisons with other clinics. We are hoping register data is used for clinical improvement programmes and, to stimulate this, for the second year in succession, we have invited clinics to participate in the project entitled "Would you like fewer post-tonsil surgery haemorrhages?". You can read more about it on page 6.

Sweden is unique in that tonsillotomy has largely replaced tonsillectomy in surgery on children with obstructive symptoms. The reason for this is the decreased morbidity with tonsillotomy compared with tonsillectomy with preserved effect on the obstructive symptoms. In 2013, 77% of children aged 1–12 years operated on for obstructive indication underwent tonsillotomy with or without adenoidectomy. This has had a positive effect on patient safety. An evaluation of data from the Swedish Tonsil Surgery Register and the Swedish Board of Health and Welfare's patient register reveals that some 40 children in Sweden avoided being hospitalised for postoperative haemorrhage in 2013, as these children underwent tonsillotomy instead of tonsillectomy.

This annual report focuses on haemorrhage following tonsillectomy. On average, 11% of patients undergoing tonsillectomy are re-admitted as a result of postoperative haemorrhages. This is a high figure and there is a relatively large spread in the frequency of haemorrhage between different units (0.5%–13.8%), which reflects that there is potential for improvement at many units. In this annual report, the data are presented separately

for tonsillectomy and tonsillotomy in order to make the results clearer. Each unit with a result that deviates negatively from the national mean value should analyse the way its surgery was performed, how its education is organised and how the collaboration between anaesthesia, wards and reception functions. A study of register data clearly reveals that applying heat to the tonsillar fossa, regardless of whether this relates to removing the tonsils or stopping a haemorrhage, sharply increases the risk of postoperative haemorrhage. This result could be of interest to units with a high haemorrhage frequency, see page 7 for more details.

Postoperative analgesia is an area in which many units need to reassess their care programmes. The register data for 2013 reveal that 17% of patients contacted the health-care service for advice on pain relief, whereas 10% received antibiotic treatment during the healing process. We believe that the prescription of antibiotics may be associated with insufficient analgesia. To improve postoperative analgesia, national guidelines for pain relief were drawn up and presented in the 2012 annual report (can be downloaded as a pdf at www.entqualitysweden.se). A new feature this year is a dosage tool for postoperative analgesia for children and it is available at www.tonsilloperation.se. This tool can be used by both caregivers and patients and provides a dosage table for analgesics during the first period following surgery.

This annual report can be downloaded as an app to a smartphone or tablet (search for "ÖNH-årsrapport" (ENT annual report) in your AppStore). All the reported data relate to tonsil surgery performed in 2013.

We would like to thank everyone who has helped to ensure that this register has so many registrations of high quality. Together, we are creating a functional register which will help us to develop health care.

The reference group in Sweden for tonsil surgery

Using register data

The long-term aim of quality registers is to improve the quality of health care. Access to data is a fundamental prerequisite for describing of the clinical process and activities, and is the foundation of clinical improvement programmes. The Swedish Tonsil Surgery Register presents data in a number of different ways and this annual report is one of them. When the data from a clinic are analysed, we recommend an initial examination of the value compass. It provides a graphic presentation of a number of indicators that describe a health-care programme in relation to a national average. Supplementary tables make it possible to analyse the data in greater detail and compare the results at one clinic with those at others. A basis is also provided for assessing the scope of the different parameters in the value compass.

The need for clinical improvement relates primarily to postoperative morbidity, first and foremost haemorrhage and pain. To facilitate and follow up developments in these areas, there are opportunities other than an annual report, which is slow to react and does not present the data for one year until the following autumn. Each clinic has the opportunity to obtain more up-to-date data in different ways at the website: www.entqualitysweden.se. After logging in with an SITHS (Swedish e-identity) card, it is possible to study the results for the clinic in real time and also download an Excel file with data for that clinic.

This Excel file can be found under "Register". It is comprehensive and may be difficult to understand in its entirety, but some information is easy to obtain. For example, in the BA (Bleed hospital) and BB (Bleed op again) columns, the patients who needed to be admitted and undergo re-operations because of haemorrhage can be identified. As the database contains Swedish personal ID numbers, it is possible specifically to analyse the course of those patients' illnesses.

This information is supplemented by the bar charts under "Statistics in real time". The number of patients who sought contact with the health-care service or were admitted because of haemorrhages during the past year can be found here and compared with the national average for both tonsillectomy and tonsillotomy.

Access to the data for individual clinics will be further improved. An app for smartphones and tablets has been developed and it will enable interactive analyses of the data from individual clinics. It will be launched during the winter.

Quality registers make it possible to deliver data to clinics to enable them to improve their health-care programmes. To realise a true improvement, we recommend that the results for a clinic should be discussed in detail at clinic meetings with everyone involved. An example of the way this can be done is given in page 6 of this annual report.

Improvement project “Would you like fewer post-tonsil surgery haemorrhages?”

Thanks to the feedback of data from the tonsil quality register, clinics are made aware of their results and are able to make comparisons with other clinics. It may sometimes be difficult to decide where to begin to reduce the frequency of haemorrhages. To support clinics that wanted to reduce the frequency of haemorrhages, the project entitled “Would you like fewer post-tonsil surgery haemorrhages?” was initiated via the reference group for tonsil surgery in the autumn of 2013. Six clinics participated and the project began with a seminar with lectures on quality improvement and a review of research related to tonsil surgery. Each participant analysed the data for his/her clinic under supervision and then drew up a plan of action. When this plan of action had been accepted by the medical director at each clinic, the changes were implemented. Typical procedures that were introduced at a number of clinics included the feedback of results and discussions between physicians. Concrete improvements could include a review of the surgical techniques and haemostasis following tonsillectomy, the organisation of the training of young physicians and information and pain relief for patients. The project ended in the spring of 2014 and the effects will be followed up via the quality register this winter. A new project with a similar design is due to begin in the autumn of 2014, with seven clinics.

Clinics and physicians who took part in the project 2013–14:

- Södra Älvsborgs Sjukhus, **Dr Hugo Davidsson**
- Centralsjukhuset i Karlstad, **Dr Anna Sjögren**
- Norrbottens läns landsting, **Dr Torbjörn Larsson**
- Skaraborgs sjukhus, **Dr Dan Öberg**
- Falu lasarett, **Dr Marek Prucha**
- Västmanlands sjukhus, **Dr Karolina Elinder**

Example from Västmanlands sjukhus

Dr Karolina Elinder from the Västmanlands sjukhus (hospital) in Västerås participated in the improvement project. Of the patients undergoing tonsillectomy in 2009–2012, an average of 15% were re-admitted to hospital due to haemorrhages. A review of the register data revealed that tonsillectomies were largely performed using ultracision or diathermy scissors, techniques which result in a greater risk of haemorrhage, according to both a number of studies and a review of the Swedish Tonsil Surgery Register (see page 7). Together with Dr Johan Knutsson and the medical director, Mats Rosén, an action plan with a specific starting date was approved. On 1 April 2014, the clinic stopped using warm surgical techniques and instead changed to a totally cold technique. This means that only instruments made of cold steel are used for dissection. Any haemorrhages are stopped with three minutes of compression, which may need to be repeated. Bleeding vessels can be ligated, while diathermy is only used in exceptional cases and then at low electric power. One important part of this improvement programme was the training of both nurses and physicians, which took place in co-ordination with the anaesthesia clinic.

From 1 April to mid-August, 38 tonsillectomies were performed and three of these patients were re-admitted because of haemorrhage. This gives a haemorrhage frequency of 7.8%, i.e. half the previous figure. It is far too soon to be able to draw any reliable conclusions, but developments so far look encouraging and we shall be following the results from Västerås with interest!

Haemorrhage after tonsillectomy

When a new surgical technique is introduced, it should be compared with the routine technique that was previously used. When it comes to tonsillectomy, the cold technique is the “gold standard” with which all new techniques should be compared (1). The reason for this is that the cold technique has been shown to be associated with the lowest frequency of late postoperative haemorrhage.

During the past decade, a number of multicentre studies have been published on the connection between the technique used for tonsillectomy and postoperative haemorrhage. They include the large British study from 2004 (2) and an Austrian study that was published in 2011 (3). Both these studies unequivocally reveal that warm techniques carry a greater risk of late postoperative haemorrhage than cold techniques. Based on the results of the British study, the authors recommend that “techniques such as diathermy and coblation ... should therefore be used with care and only after suitable training” (2). This has also been suggested by other authors. In a review of publications on surgical techniques used for tonsillectomy (4), the authors come to the conclusion that “surgical techniques for tonsillectomy that should probably cease to be used comprise monopolar diathermy, coblation, laser and the harmonic scalpel”.

Is this relevant to Swedish conditions? The British and Austrian results are confirmed by analyses of the Swedish Tonsil Surgery Register. Compared with a totally cold technique (no heat or electricity in connection with either dissection or haemostasis), the risk of re-admission as a result of haemorrhage is 2.8 times higher in conjunction with the use of cold dissection with diathermy for haemostasis, 3.2 times higher using the coblation technique, 4.3 times higher with diathermy scissors and 5.6 times higher using ultracision.

As this report reveals, a number of different techniques are used for both dissection and haemostasis in connection with tonsillectomy in Sweden. The re-admission frequency as a result of postoperative haemorrhage varies between 0% and more than 15%. One of the purposes of this annual report is to present the results from each

clinic and offer every clinic an opportunity to compare its results with those of others in order to stimulate improvement programmes whenever necessary. This is illustrated by the improvement project in Västerås, which is presented on page 6.

Based on current knowledge, it is reasonable to recommend that all ENT physicians during training are given the chance to learn to perform tonsillectomy using a totally cold technique, without using any form of heat, including diathermy. Only when the cold technique has been mastered can hot instruments be used. The warm technique can have advantages, such as fewer postoperative haemorrhages and shorter operating times.

Regardless of the technique that is chosen, each clinic needs to keep a constant check on its results and, whenever necessary, change its techniques.

Completeness

The Swedish Tonsil Surgery Register has now reached an important point. In 2013, our coverage level was 81.4%, which means that, of 13,811 known tonsil operations, 11,238 were registered in the quality register. It is also pleasing to report that 17 clinics register more than 90% of their tonsil operations in the register.

How completeness is calculated

The calculations have been performed in collaboration with the Register Service at the Swedish Board of Health and Welfare. Patients undergoing surgery and registered with surgery numbers EMB10, EMB15, EMB20 or EMB99, combined with a non-malignant diagnosis, have been identified in the Patient Register (PAR) and matched, via their personal ID numbers, against the National Quality Register in Sweden (NTSRS).

The following results of this matching process are presented.

- Total number of patients undergoing surgery in Sweden. This column is a synthesis of individual data from both the NTSRS and the PAR.
- Completeness level, i.e. the percentage of patients in the NTSRS from all those undergoing tonsil surgery in Sweden.
- Number of patients in the NTSRS
- Number of patients in the PAR
- Number of patients only listed in the NTSRS
- Number of patients only listed in the PAR

Results

A total of 13,811 tonsil operations are registered in the patient register or the quality register. There are 13,263 patients registered in the patient register, while the quality register contains 11,238 valid patients. There are 1,022 more registrations in the quality register compared with 2012. In some cases, patients are registered in the quality register but not in the patient register (n=548), but the opposite also applies (n=2,573). Matching the two registers reveals that a total of 13,811 (known) tonsil operations were performed in 2013, making the completeness level 81.4%. In all, 64 units in Sweden perform surgery and, of these, 53 participated in the register in 2013, making a participation rate of 83%.

FACTS BOX:

The coverage level is given at both individual level (completeness), i.e. the percentage of patients in the quality register of all the patients undergoing tonsil surgery in Sweden, and at clinic level, i.e. the percentage of participating clinics of all those performing tonsil surgery (participating percentage/coverage).

New value compasses

The value compasses comprise 10 variables and are produced to provide a quick, pedagogic overview. One new feature this year is that the results for tonsillectomy and tonsillotomy respectively are presented separately in the value compasses. All the data that are presented in the value compasses come from the quality register.

The value compass should be used as a qualitative indicator of health care. Its simplified signal system is able to identify areas in which it is necessary to conduct more in-depth analyses of data that can be found in other parts of the report.

The values for the clinic are shown in green, while red represents the national average. The limit values on each axis represent the largest and smallest value for a variable. Please note that the scales on each axis therefore differ depending on the maximum or minimum value of the variable. The lowest value for the variables is at the zero point and the highest is on the periphery. A clinic with red fields has a poorer value than the national average for the variable in question. The values that form the basis of the individual axes in the value compass are presented next to the axes.

Next to the value compasses, there is a table showing coverage, the response frequencies for the questionnaires and the percentage of registered e-mail addresses. A different signal system is used for these variables to describe the quality of the register work at each clinic.

Coverage:

 Coverage > 80%

 Coverage 70–80%

 Coverage < 70%

Response frequency:

 > 50% response frequency to patient questionnaires

 40–50% response frequency to patient questionnaires

 < 40% response frequency to patient questionnaires

Percentage of e-mail addresses

 > 75% have given e-mail addresses

 < 75% have given e-mail addresses

The variables that are presented for tonsillectomy and tonsillotomy respectively

- **Re-admitted because of haemorrhage** – the percentage of patients who reported that they were re-admitted to hospital because of postoperative haemorrhage.
- **Re-operation because of haemorrhage** – the percentage of patients who reported that they had undergone a re-operation because of postoperative haemorrhage.
- **Contact because of pain** – the percentage of patients who reported that they had needed to make unplanned contact with the health-care service because of postoperative pain.
- **Freedom from symptoms** – the percentage of patients who reported that “my problems have disappeared” or “I have recovered fairly well from my problems”.

The variables that are presented for all tonsil surgery

- **Perceived patient information** – the percentage of patients who reported that the information they received prior to surgery matched their perception of surgery and the following period.
- **Percentage of TT obstruction 0–12 years** – the percentage of patients undergoing tonsillotomy (TT) of those undergoing surgery for the indication of obstruction and are 0–12 years of age.

Units with fewer than 30 registered operations are excluded from presentations of the value compasses.
TE=tonsillectomy or tonsillectomy with adenoidectomy
TT=tonsillotomy or tonsillotomy with adenoidectomy

Contact with health care

The questionnaires that are sent to patients/close relatives 30 days after surgery asking whether they needed to contact health care as an unplanned measure following surgery. This table lists the number of patients who answered the questionnaires. It shows the number and percentage of patients who needed to contact health care because of haemorrhage, pain and infection, together with the degree to which these patients received antibiotic prescriptions.

Table 2. Unplanned contact with health care following surgery.

County council	Hospital	Contact due to bleeding, infection or pain. Numbers (%)	Contact due to bleeding. Numbers (%)	Contact due to pain. Numbers (%)	Contact due to infection. Numbers (%)	Received antibiotic treatment. Numbers (%)

Other information

This table lists the percentage of day surgery for tonsil surgery at each clinic. The table also shows the percentage of tonsillotomies that were performed on children aged 1-12 with the indication of obstruction. The last column shows the number and percentage of patients who answered “yes” to the question “Did the information you received match your perception of surgery and the following period?”.

Table 3. This table lists the number and proportion of day surgery for tonsil surgery at each clinic. The table also shows the number and proportion of tonsillotomies performed in children 0-12 operated on due to obstruction. The last column shows the number and percentage of patients that perceived that the patient information was accurate.

County council	Hospital	Outpatient surgery, numbers (%)	Percentage of TT obstruction 0-12 years, numbers (%)	Perceived that patient information was accurate, numbers (%)

Response frequency and the percentage of e-mail addresses

All patients undergoing tonsil surgery are asked to answer a patient questionnaire 30 days and six months respectively after tonsil surgery. To ensure that the information from the two patient questionnaires is representative, it is necessary to have a high response frequency and this frequency is presented in the table. It is important to inform the patient that the health care in conjunction with tonsil surgery is followed up with questionnaires and that it is important that the patient answers them.

In the quality register, there is a function that enables patients to answer the questionnaires using a unique web link which is sent by e-mail. This saves the clinic a great deal of work when it comes to administering the paper questionnaires. The table lists the percentage of registered e-mail addresses at each clinic. Many clinics can increase the percentage of e-mail addresses that are registered and a review of the importance of filling in the e-mail address on the first form is recommended. Another way of obtaining e-mail addresses could be to ask for them in the health declaration/informed consent at the clinic.

Table 4. Response rate, for patient questionnaires at each clinic. The last column shows the percentage of patients e-mail addresses registered for each clinic.

County council	Hospital	Patient questionnaires		E-mail addresses registered Numbers (%)
		30 days Numbers (%)	6 months Numbers (%)	
Total for Sweden		5926 (52.7)	3708 (33)	6923 (61.5)

Indications

There are two main groups of indications for tonsil surgery, infection/inflammation and obstruction/snoring/hypertrophic tonsils.

The table presents indication statistics for each clinic from the quality register. The variation between the clinics is substantial, in terms of both the percentage of obstruction indications and within the infection/inflammation indication group.

Knowledge of the distribution of indications at an individual clinic is important when analysing the complication and result data. For example, a high percentage of infection indications is probably associated with a high percentage of tonsillectomies in the adult population, with an expected higher complication frequency.

The spread of indications could be a true description of the real-life situation caused, for example, by demographic differences or local traditions. This is probably the case when it comes to the variation in the percentage of obstruction.

Another explanation is shortcomings in the ICD-10 coding system. Chronic tonsillitis is coded as J350. This code is also used for recurring tonsillitis, as there is no separate code for this diagnosis.

A registration in the quality register based on diagnosis codes alone therefore leads to an excessively high frequency for the diagnosis of chronic tonsillitis. We therefore recommend that a physician who decides on tonsil surgery should also document the indication, as the indications of chronic tonsillitis and recurring tonsillitis are separate in quality registration.

We recommend that all clinics should review their routines for the way surgery indications are registered in the Swedish Tonsil Surgery Register. The following definitions should be used.

Airway obstruction/snoring/hypertrophic tonsils: breathing disturbances during sleep caused by the tonsils

Recurrent tonsillitis: at least three episodes of acute tonsillitis during the past 12 months

Peritonsillitis: an incipient peritonsillar abscess or a peritonsillar abscess with pus which undergoes acute surgery or if the indication is previous peritonsillitis

Chronic tonsillitis: long-term inflammation in the tonsils (at least three months) to a degree that impacts daily activities

Systemic complications of tonsillitis: systemic illness that is exacerbated by a bout of tonsillitis, such as psoriasis

Table 5. Indication for tonsil surgery 2013.

NO ONE PERFORMS SURGERY LIKE US

The NTSRS describes the entire process in tonsil surgery. Is there anything that can be improved at your unit?

Enlarged tonsils

Tonsillectomy

Tonsillotomy

Postoperative haemorrhage

Postoperative haemorrhage is the most serious complication following tonsil surgery, since it can lead to re-admission, sometimes to re-operation and, in rare cases, contribute to death.

This chapter presents information on early haemorrhage, i.e. haemorrhage during the hospitalisation period that leads to active measures by the physician, and late haemorrhage, i.e. haemorrhage following discharge to the patient's home.

Information on early haemorrhage comes from the second questionnaire in the register and is reported by the hospital/professional.

Information on re-admission because of haemorrhage comes from the patient. At clinics performing a small number of operations, or with a low response frequency, these results can be very uncertain. Information on the frequency of late haemorrhage must therefore always be interpreted, while simultaneously analysing surgery volume and response frequency.

To obtain more reliable information on re-admission because of haemorrhage following tonsil surgery, the data in the quality register have been matched, at individual level, against the Patient Register (PAR), Swedish National Board of Health and Welfare. To perform this matching, all the care interventions registered in the PAR within 30 days after tonsil surgery, with a diagnosis and/or surgery number that matches post-tonsil surgery haemorrhage, are used.

This analysis has been conducted by the National Board of Health and Welfare's register service and the compilation in the table shows the number and percentage of patients who were re-admitted according to the quality register or the PAR and how well the information matches in the individual registers.

- Number of re-admissions because of haemorrhage registered in the NTSRS
- Number of re-admissions because of haemorrhage registered in the PAR
- Number of patients who are only listed in the NTSRS
- Number of patients who are only listed in the PAR
- Number and percentage of patients who are listed in either the PAR or the NTSRS

This matching was conducted on 24 October 2013 with PAR3 using data from the quality register from 18 August 2014 against data from 2013. The table shows all the units which reported to the PAR or the NTSRS.

We have previously reported data from the PAR and the quality register separately. With the design we are using this year, we hope that we are presenting more correct values for the "re-admitted because of haemorrhage" quality indicator.

Figure 1. This figure shows the longitudinal haemorrhage frequency for each surgical method. The information has been taken from the quality register for tonsil surgery.

Table 6. Postoperative haemorrhage occurring during admission for tonsil surgery (primary or early haemorrhage). Primary haemorrhage is defined as action (medical or return to theatre) taken by physician and is recorded by the professional in the NTSRS.

Different kinds of tonsil surgery

In conjunction with tonsil surgery, two basically different types of surgery can be performed, tonsillectomy or tonsillotomy. Tonsillectomy involves the total removal of the tonsils. Tonsillotomy involves the partial removal of the tonsils, leaving a bed of tonsillar tissue.

Surgical codes used (according to the Nordic Medico-Statistical Committees) Classification of Surgical Procedures

- **EMB10** for only tonsillectomy
- **EMB20** for tonsillectomy with simultaneous adenoidectomy/abrasion
- **EMB15** for only tonsillotomy
- **EMB15+EMB30** for tonsillotomy with simultaneous adenoidectomy/abrasion

Surgical techniques

In Sweden, a number of different surgical techniques are used in tonsil surgery. The following surgical techniques can be registered in the quality register.

Cold steel – the dissection is performed with “cold” instruments, such as a scalpel, scissors or an elevator.

Radio frequency – in all radio-frequency techniques, the radio-frequency energy is used to achieve a cutting, dissecting, volume-reducing or coagulating effect.

A review of the register data reveals that four different radio-frequency instruments are used:

- Arthrocare-Coblation®
- Ellman-Surgitron®
- Sutter-Curis®
- Olympus-Celon

Diathermy scissors – surgery is performed with scissors which can simultaneously supply bipolar diathermy over the blades of the scissors. In this way, the instrument is able to divide and coagulate tissue simultaneously.

Ultracision – Harmonic Scalpel®. Surgery is performed with an instrument that divides and coagulates tissue simultaneously. The technique is based on ultrasonic vibration.

Laser – surgery is performed with a laser beam, most frequently a carbon-dioxide laser, which divides and coagulates tissue simultaneously.

Miscellaneous – to obtain knowledge of the other techniques that are used, there is a Miscellaneous field. The information in this field will form the basis of future reviews of this quality register. It has, for example, emerged that, at some clinics, the tonsils are dissected and removed using bipolar diathermy and this should therefore be registered here.

Haemostasis techniques

In Sweden, a number of different techniques for achieving haemostasis are used in tonsil surgery. The following haemostasis techniques can be registered in the quality register.

Infiltration anaesthesia with adrenaline – the haemostasis effect is achieved through the vascular-constricting effect of the adrenaline.

Unipolar (monopolar) diathermy – the haemostasis effect is achieved through the heat coagulation of blood vessels. The current is conducted through the patient's tissues to a neutral plate (earth).

Bipolar diathermy – the haemostasis effect is achieved through the heat coagulation of blood vessels. Bipolar instruments (scissors, forceps and so on) have two poles and the current is conducted from one pole to the other. Current does not pass through the patient's other tissues.

Laser – the haemostasis effect is achieved by applying high, local heat.

Ligature – this involves using a knotted ligature of the “tonsillar stalk” which can typically occur in the lower pole of the tonsils. The idea is to block a group of blood vessels with a ligature. It may also involve tying a knot around bleeding vessels.

Suture ligature – this means staunching the blood – in other words, performing a deep suture with a needle in the soft tissue to stop bleeding.

The alternatives “none” and “other” can also be used.

Benefit of tonsil surgery

The quality register measures the patient's assessment of the benefit of surgery. This is obtained by asking the patient to answer a questionnaire six months after surgery and assess the degree of freedom from symptoms, see the questionnaires on page 60.

The patient's perception of freedom from symptoms can be based on a range of factors, apart from the actual surgery, which are not measured in the quality register. It is reasonable to suppose that there is a link between the degree of freedom from symptoms and the problems the patient experienced prior to surgery, but the results can also be impacted by the application of the indications for tonsil surgery, any complications after surgery and the information the patient was given before and after surgery.

The benefit of tonsil surgery has been reported every year in the ENT quality register's annual reports. In the past few years, the percentage of patients answering "My symptoms are gone" or "My symptoms are almost gone" has remained stable at around 96%. The differences between clinics have been small (91–100%), with no statistically or clinical significant differences.

This year, we have chosen to present "The benefit of tonsil surgery" divided between indications at national level. The indications of recurrent tonsillitis and chronic tonsillitis have been combined. When it comes to respiratory obstruction/snoring/tonsillar hypertrophy, tonsillotomy and tonsillectomy are reported separately. Not unexpectedly, the patients who have undergone surgery for peritonsillitis report very large freedom from symptoms. The degree of freedom from symptoms is also very large for other infection-related indications. The lowest percentage of patients with freedom from symptoms can be found in the group undergoing surgery for "Other symptoms". Small differences in freedom from symptoms can be seen in the obstruction group, depending on whether tonsillectomy or tonsillotomy was performed.

At clinic level, the data have been gathered together for the entire tonsil surgery group, as the low response frequency does not permit the presentation of subgroups. We recommend that all clinics should compare their figures with the national average. A percentage of satisfied patients that is smaller than the national average should result in a more in-depth local analysis.

Figure 3. Proportion of symptom relief related to indication for tonsil surgery.

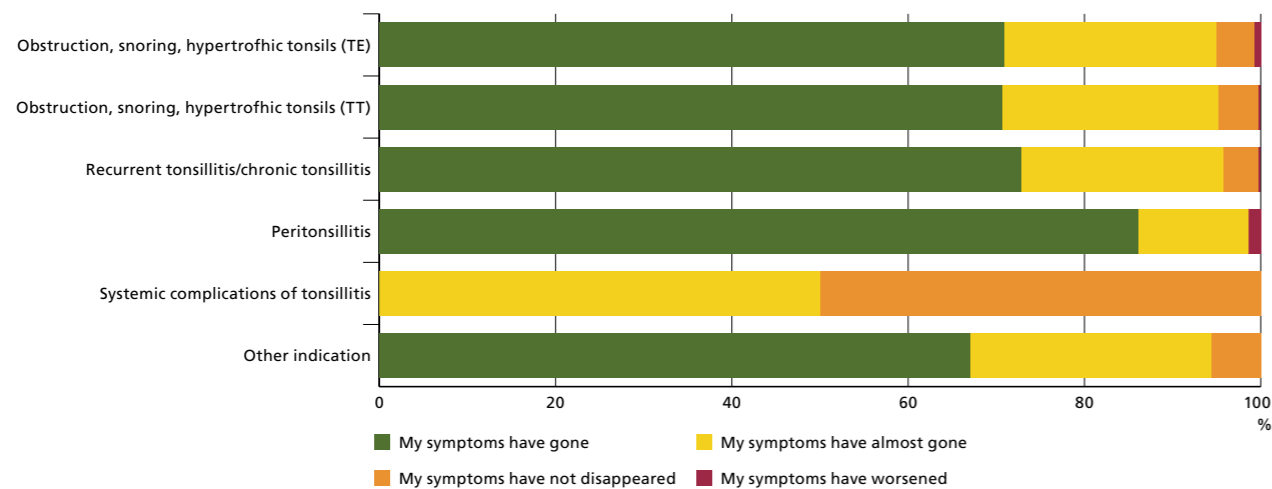

Figure 4. Proportion of patients reporting "My symptoms are gone" or "My symptoms have almost gone" six months after tonsil surgery. The results are from surgeries performed in 2013.

Questionnaires in the Swedish Tonsil Surgery Register

Data for the quality register are collected using four questionnaires. The first two are completed by the medical profession. They contain information on indications, information regarding daycare/hospitalisation, surgical method (such as tonsillectomy) and surgical technique (such as cold steel) and technique used for haemostasis.

Patients are asked to complete two questionnaires. The first is despatched 30 days postoperatively and it identifies any haemorrhage, pain and infection. This questionnaire also asks whether the information the patient was given matched his/her experience. The second questionnaire is despatched six months after surgery and identifies the degree of freedom from symptoms. These patient questionnaires should be despatched in the form of a web link via e-mail to reduce administration. It is therefore important that patients are asked to enter their e-mail addresses on the first questionnaire.

TONSIL SURGERY PRE-OP SURGERY FORM To be completed by the surgeon

Patient name: Date of birth:
 E-mail:
 Date:

Main Indication (only one selection)

- Airway obstruction / snoring / hypertrophic tonsils
- Recurrent tonsillitis
- Quinsy
- Chronic tonsillitis
- Complication to tonsillitis
- Other:

Secondary Indikation (only one selection)

- Airway obstruction / snoring / hypertrophic tonsils
- Recurrent tonsillitis
- Quinsy
- Chronic tonsillitis
- Complication to tonsillitis
- Other:

Doctor's Name:

PATIENT QUESTIONNAIRE Answered by patient or caregiver 30 days postoperatively

Tonsil surgery was performed on you or your child about 30 days ago. In order to improve the quality of the health services it is important to know if any complications have occurred after the surgery. We appreciate your answer also when everything has been uncomplicated. If you are a caregiver we would like you to try to answer the questions as you believe your child would have answered.

Patient name: Date of birth:
 E-mail: Date:

You who fill in the questionnaire is the operated caregiver / other

Have you contacted health services because of bleeding from the throat? Yes No
 If yes – how many days after the operation?

Have you been admitted to hospital due to bleeding from the throat? Yes No
 If yes – what hospital were you admitted to?

Was there any infection within 30 days of the operations? Yes No
 If yes – what kind of infection?

Did you contact health services due to the infection? Yes No
 Did you receive antibiotics due to the infection? Yes No

Have you contacted health services due to pain after the operation? Yes No

How many days after the operation did you take pain killers?

How many days after the operation did you start eating regular food?

Has the information you received preoperatively been in accordance with your experiences of the operation and postoperative period? Yes No
 If no – what was not correct?

Have you used the web site www.tonsilloperation.se? Yes No

PATIENT QUESTIONNAIRE Answered by patient or caregiver 6 months postoperatively

Tonsil surgery was performed on you or your child about 6 months ago. In order to improve the quality of the health services it is important to receive information on how your or your child's symptoms have changed after the surgery. If you are a caregiver we would like you to try to answer the questions as you believe your child would have answered.

Patient name: Date of birth:
 Date:

You who fill in the questionnaire is the operated caregiver / other

Check the square that best corresponds to your or your child's situation:

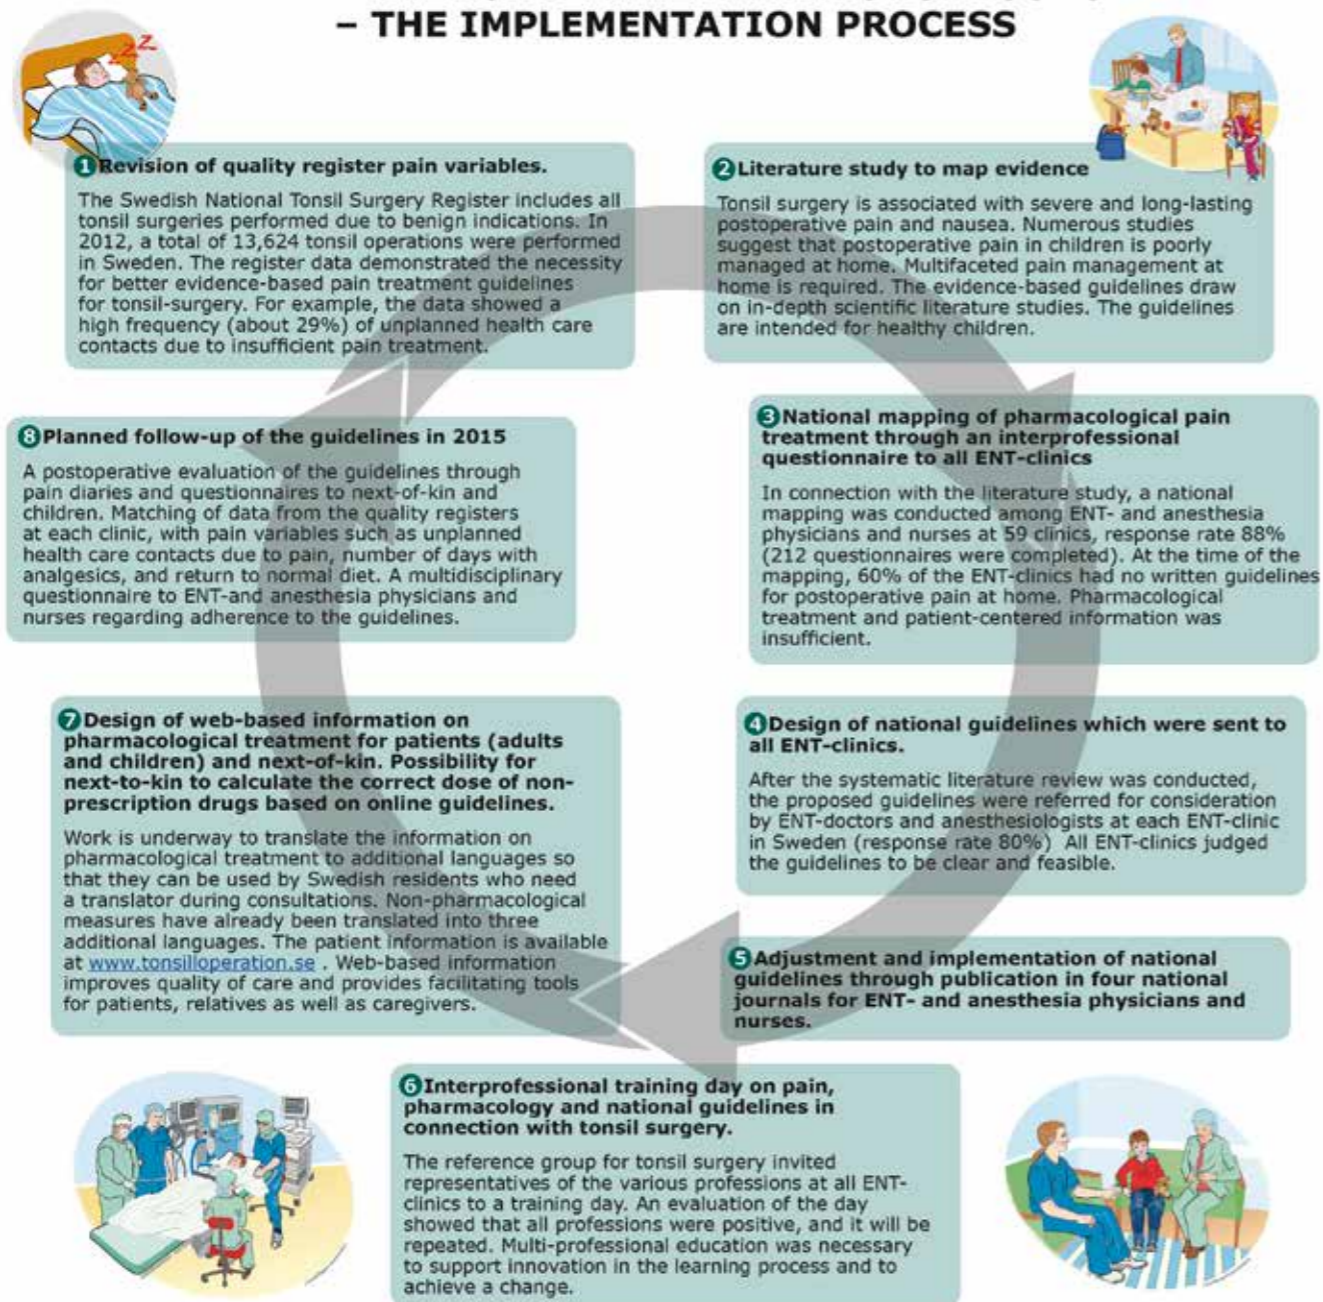

- The symptoms are gone
- The symptoms are almost gone
- The symptoms remain
- The symptoms have increased

Have any new symptoms appeared? Yes No

If yes, what symptoms?

Comments:

NATIONAL GUIDELINES FOR PHARMACOLOGICAL TREATMENT IN CHILDREN AFTER TONSIL-SURGERY – THE IMPLEMENTATION PROCESS

www.tonsilloperation.se

www.tonsilloperation was launched in May 2012 with information for patients undergoing tonsil surgery. The information on this website has been collated following a systematic review of information material from all ENT clinics, literature studies and interviews with children undergoing tonsil surgery (and their parents). On this website, there is information aimed at children, including a story with a narrator and illustrations, as well as information for caregivers and adult patients. The texts on the website were translated into English, Spanish and Arabic at the beginning of 2014. The stories have also been translated into English.

At the beginning of 2014, the website was developed to include information for patients relating to postoperative pain relief. This is a unique tool, as it is possible to use the website to obtain individualised dosage tables (see below).

Use of the www.tonsilloperation.se website has continued to increase from around 500 visitors/month in the autumn of 2012 to 8,000 visitors/month in August 2014 (Figure 5). On average, the website has been visited 300 times a day in 2014. Until August 2014, it had been visited 50,000 times, of which 41,000 were “new visits” (Figure 6). About half the visitors are outside Sweden. The website was translated into several languages to increase its availability to patients who do not speak Swedish. As a result, this website is now used all over the world and Saudi Arabia is the country with most users besides Sweden.

Figure 6. Percentage of new visits and return visits

Eighty-one per cent found the website via Google, 16% went to the website directly and some 2% were linked via 1177 (the national healthcare's trusted medical information on the internet). In the vast majority of cases (90%), the information used was aimed at children and caregivers, while the remaining visitors used information aimed at adults.

We can see that a large percentage of the patients undergoing tonsil surgery use the website. In the 30-day questionnaire, in 2013, 35% said that they had “consulted www.tonsilloperation.se”. For the period Jan-Aug 2014, the corresponding figure was 44%.

The website has been adapted for use on smartphones and tablets. An analysis of the type of unit that has been used to visit the website reveals that 57% have used smartphones, 33% computers and 9% tablets (2014).

Figure 5. Number of visits to www.tonsilloperation.se in 2012–2014

The website also gives advice on pharmacological pain relief for children. A caregiver can read about pain relief, pain assessment and pain assessment scales that can be used at home. The recommended treatment with OTC drugs (COX inhibitors and paracetamol) is described, together with possible restrictions and side-effects. On the website, a caregiver can calculate dosages according to a child's weight. The recommended treatment period and reduction of the drug dosage are made clear. The website also informs readers to contact the health-care service in the event of major difficulty consuming fluid. All the information and the dosage schedule can be downloaded as a PDF file for printing. The PDF file is designed in such a way that caregivers can see a dosage table (Figure 7) based on the choices they have made.

The reference group recommends that there should be a link to www.tonsilloperation.se on ENT clinic information sheets.

Figure 7. Example of part of the dosage schedule caregivers can obtain from tonsilloperation.se when calculating OTC drugs according to guidelines on the basis of the choices they have made

Example of dosage schedule: The caregiver has indicated that the child is healthy, has no allergy, underwent surgery on 9 September, weighs 20 kg and that COX inhibitors, ibuprofen (alternative choice diclofenac) and a preparation of paracetamol (mixture) and COX inhibitors (suppositories) were chosen.

Drug	Days 1–3	Days 4–8
If the date of surgery was changed, please complete again!	9 September 2014-11 September 2014	12 September 2014-16 September 2014
Ibuprofen	1 tablet 4 times a day	1 tablet 4 times a day
	Suppositories 125 mg	Suppositories 125 mg
Paracetamol	20 ml 4 times a day	15 ml 4 gånger per dag
	Mixture 24 mg/ml	Mixture 24 mg/ml

IMPORTANT

- The recommended doses in the table are higher than the amounts on the drug packaging. These doses should **ONLY** be given if **YOUR CHILD IS ABLE TO DRINK LARGE QUANTITIES**.
- Contact the health-care service if your child has major problems consuming fluid and is experiencing pain in spite of the regular intake of the recommended medication.
- Contact the health-care service **IMMEDIATELY** in the event of any haemorrhage in the throat.

Visiting clinics

Following our excellent experience from 2012, the reference group for tonsil surgery, represented by Joacim Stalfors and Lotta Hessén Söderman, made a number of visits to clinics in 2013 and during the spring of 2014.

The aim of these visits was to make personal contact with clinic directors and physicians and secretaries responsible for the register, to answer questions, validate data by taking random samples from registrations and compare them with data from medical notes. In conjunction with these visits, we also offered lectures, which we sometimes held for the physicians and sometimes for all the staff. In Jönköping and Halmstad, we took part in a complete quality day. We were also able to attend operations and see how the physicians used their techniques. Prior to each clinic visit, we helped to produce the data for the clinic in question and, at a number of clinics, extremely positive results from improvement programmes have been presented.

The clinics we visited in 2013 and during the spring of 2014 were:

Falun
 Karlskrona
 Västerås
 Kalmar
 Sahlgrenska
 Örebro
 Karlstad
 Jönköping
 Sophiahemmet
 Skärholmen
 Ängelholm
 Trelleborg
 Kristianstad + Ystad via videoconference
 Helsingborg

In overall terms, we were given an excellent reception and top-class care and we hope to be able to continue these visits. We shall soon have visited all the high-volume clinics and we eventually plan to offer return visits, if an improvement programme has been run and help is needed with feedback, for example. We should like to take this opportunity to offer you the chance to contact the reference group via joacim@stalfors.se if you are interested in a visit!

Dr Anna-Lena Roos is performing tonsillectomy with radiofrequency at Sahlgrenska University Hospital.

Reference group for tonsil surgery

The reference group for tonsil surgery has been tasked by the Swedish association for otorhinolaryngology and head and throat surgery to manage, develop and provide feedback on the Swedish Tonsil Surgery Register. The register is funded by the Swedish Association of Local Authorities and Regions.

The members of the reference group are:

Register Director **Joacim Stalfors**, senior consultant, MD, associate professor, ENT Clinic, Sahlgrenska University Hospital, Gothenburg (joacim.stalfors@vgregion.se)

Elisabeth Ericsson, RSN, university lecturer, associate professor, Institute of Health Science and Medicine, Örebro University

Claes Hemlin, senior consultant, MD, Ph.D, Sollentuna sjukhus, Stockholm

Anne-Charlotte Hessén Söderman, senior consultant, MD, Ph.D, Aleris specialist care, Sabbatsberg Hospital, Stockholm

Erik Odhagen, senior consultant, MD, Ph.D student, ENT Clinic, Sahlgrenska University Hospital, Gothenburg

Ola Sunnergren, senior consultant, MD, Ph.D, ENT Clinic, Ryhov County Hospital, Jönköping

Left to right: Lotta Hessén Söderman, Ola Sunnergren, Joacim Stalfors, Elisabeth Ericsson, Claes Hemlin and Erik Odhagen

Centre of Registers Västra Götaland
Centre for National Quality Registers

Centre of Registers Västra Götaland provides a variety of services for the management and development of national quality registers and supports affiliated researchers. It is one of several Swedish register centres. It enables new registers to benefit from the experience accumulated by older ones and offers advanced expertise in the areas of statistics and information technology. The centre's development managers take charge of publishing its annual reports and coordinate support for the activities of the various registers.
